

The difference between GUI and CLI is that the files are displayed on our computer screens. The desktop of our computer is meant to mimic the real world desk space where we keep all of our files, papers, pictures, and whatever else. On that desk we can organize our stuff by putting it in folders to condense these items so that they are not taking up our whole desk space, which is what the GUI does for us on our computers. It takes the same concepts, and puts it into a related visual aid so that you can place and name your files accordingly and then organize them. It makes it easy to find these too by giving small pictures of what the file is, its file type tag, as well as other accessible info. The CLI is quite different than, and can be best described as lines of text detailing or responding to commands. It tells instead of showing like GUI would do, just giving us the names of the files in whatever directory that we are viewing. This process of using CLI however gives you more control as to what you want to do with your computer, where GUI gave you set interactions mainly based on clicks of your mouse.
